DigiWELL

Introduction

- Majority of digital media effects research has been based on self-reported estimates (Dienlin & Johannes, 2020)
- Accuracy and validity of self-reported measures of digital media use has been recently questioned (Parry et al., 2021)

- Inaccuracy often related to central variables in question (e.g., media use itself, well-being) (Araujo et al., 2017; Sewall et al., 2020)

Introduction

Tkaczyk et al., 2024

- Our recent study on adolescent sample follows the trend
 - between $r = .40$
 - within $r = .29$
- mean discrepancy = -32 mins
- discrepancy ICC = $.56$

Introduction

- To address the limitations of prior research, we examined potentially relevant factors that may affect:
 - Convergent validity
 - Discrepancy

Between-person	Within-person
Overall smartphone use	
Mobile control self-efficacy	
Screen time fragmentation	Screen time fragmentation
Overall compliance	Daily compliance
	Weekend vs. weekdays
	Day of study

DigiWELL

Methods

- **Experience sampling method (ESM)**

- 14 days – 4 surveys per day
 - Semi-random time frames
- Digital trace of smartphone use (every second)
- Custom built smartphone app

Morning

Daily I

Daily II

Evening

- Self-reported smartphone use assessed in **evening surveys**:

“For how long you were using your smartphone (including phone-calls, being-online, playing games, listening to music, etc.) during the day (up to this questionnaire). Enter the hours and minutes (e.g. enter 5.5 hours as 05:30).”

DigiWELL

Methods

- **Sample – N = 132**, 58 % boys, 13 to 17 y. o., Czech
 - 812 daily observations
 - overall compliance rate: 72%
- Study part of the larger research project (EXPRO) (Elavsky et al., 2022)
 - four measurement bursts (per 14 days)
 - we used data from the third burst

DigiWELL

Analysis

- We built two **multilevel linear models**:
 - **Convergent validity model**
 - Validity: digital trace \rightarrow self-report
 - Within-person level interactions
 - Cross-level interactions: predictors \rightarrow random slope (validity)
 - Random intercept and random slope terms (with cov)
 - **Discrepancy model**
 - Discrepancy = | digital trace – self-report |
 - Main effects without interactions
 - Random intercept and random slope terms (with cov)
 - Robustness check using complementary model with log-transformed discrepancy

DigiWELL

Analysis

- Bayesian estimation in Mplus
 - MCMC, Gibbs sampling
 - 4 chains, 200k iterations
 - Default priors: $\beta, \tau \sim N(0, \infty)$; $\psi \sim IW(0, -3)$ or $IG(-1, 0)$

plus8

Results

Overall smartphone use

- Positive relationship with discrepancy ($\beta = .25$)
- Heavy smartphone users tend to underestimate their usage more severely than lighter users (Sewall et al., 2020)

Mobile control self-efficacy

- No non-negligible effect

Results

Smartphone use fragmentation

- Measured by **time per interaction**
 - $TPI = \text{screen time} / \# \text{ interactions}$
- Less within-person fragmentation related to more discrepancy ($\beta = .18$)
- Opposite to our hypothesis and prior evidence

Compliance with the study protocol

- Undirect measure of the motivation to participate
- No non-negligible effects on either between or within-person level

Results

Weekend vs. weekdays

- No non-negligible effects

Day of study

- Two concurrent hypotheses
 - learning effect and fatigue effect (Verbeij et al., 2021)
- Decreasing convergent validity with increasing days ($\beta = -.07$)
 - Suggesting fatigue effect

Results

Conclusions

- The nuanced daily variations underscore the complexity of measuring digital behavior
- highlighting the importance of context in the understanding of self-reported smartphone use
- These findings are particularly relevant for future research designs on the effects of digital media use

Limitations

- Digital trace data are not „objective“ or exact measure of smartphone use behavior – measurement error
- Low power for between-person effects
- Limited generalizability
